Controller synthesis

Setting:

- > a reactive **system** to *control*,
- > an interacting environment,
- □ a specification to enforce.

Controller synthesis

Setting:

- a reactive system to control,
- an interacting environment,
- > a **specification** to *enforce*.

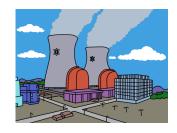

- For **critical** systems (e.g., airplane controller, power plants, ABS), testing is not enough!
 - ⇒ Need formal methods.

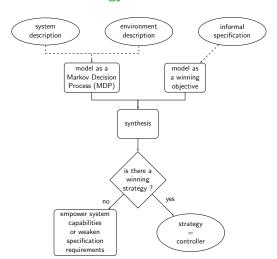

Controller synthesis

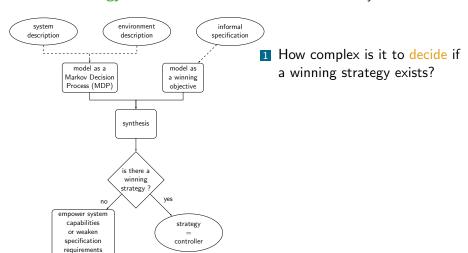

Setting:

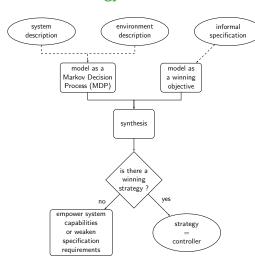

- > a reactive **system** to *control*,
- > an interacting environment,
- > a **specification** to *enforce*.

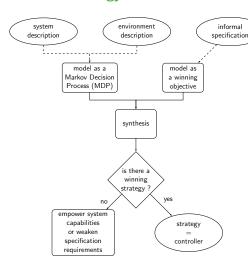

- For **critical** systems (e.g., airplane controller, power plants, ABS), testing is not enough!
 - ⇒ Need formal methods.
- Automated synthesis of provably-correct and efficient controllers:
 - mathematical frameworks.
 - \hookrightarrow e.g., game theory [GTW02, Ran13, Ran14]
 - software tools.

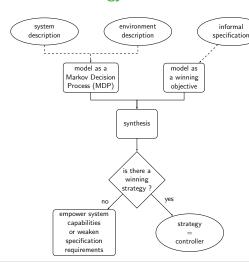

- 1 How complex is it to decide if a winning strategy exists?
- 2 How complex such a strategy needs to be? Simpler is better

- 1 How complex is it to decide if a winning strategy exists?
- 2 How complex such a strategy needs to be? Simpler is better.
- 3 Can we synthesize one efficiently?

- How complex is it to decide if a winning strategy exists?
- 2 How complex such a strategy needs to be? Simpler is better.
- 3 Can we synthesize one efficiently?
- ⇒ Depends on the winning objective, the exact type of interaction, etc.

Aim of this talk

Flavor of \neq types of **useful strategies** in stochastic environments.

- □ Joint paper¹ with J.-F. Raskin (ULB) and O. Sankur (IRISA, Rennes) [RRS15b]
- Full paper available on arXiv: abs/1411.0835

¹Invited talk in VMCAI 2015 - 16th International Conference on Verification, Model Checking, and Abstract Interpretation.

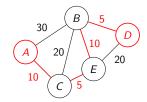

Aim of this talk

Flavor of \neq types of **useful strategies** in stochastic environments.

- □ Joint paper¹ with J.-F. Raskin (ULB) and O. Sankur (IRISA, Rennes) [RRS15b]
- Full paper available on arXiv: abs/1411.0835

Applications to the shortest path problem.

→ Find a path of minimal length in a weighted graph (Dijkstra, Bellman-Ford, etc) [CGR96].

¹Invited talk in VMCAI 2015 - 16th International Conference on Verification, Model Checking, and Abstract Interpretation.

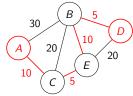

Aim of this talk

Flavor of \neq types of useful strategies in stochastic environments.

- □ Joint paper¹ with J.-F. Raskin (ULB) and O. Sankur (IRISA, Rennes) [RRS15b]
- Full paper available on arXiv: abs/1411.0835

Applications to the shortest path problem.

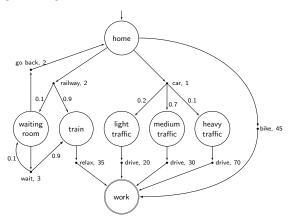

What if the environment is **uncertain**? E.g., in case of heavy traffic, some roads may be crowded.

¹Invited talk in VMCAI 2015 - 16th International Conference on Verification, Model Checking, and Abstract Interpretation.

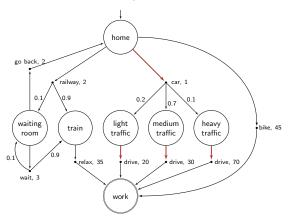

Planning a journey in an uncertain environment

Each action takes time, target = work.

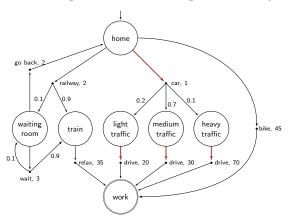

What kind of strategies are we looking for when the environment is stochastic (MDP)?

Solution 1: minimize the expected time to work

- ▷ Simple strategies suffice: no memory, no randomness.
- ightharpoonup Taking the car is optimal: $\mathbb{E}_D^{\sigma}(\mathsf{TS}^{\mathsf{work}}) = 33$.

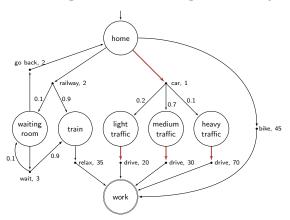

Solution 2: traveling without taking too many risks

Minimizing the *expected time* to destination makes sense **if** we travel often and **it is not a problem to be late**.

With car, in 10% of the cases, the journey takes 71 minutes.

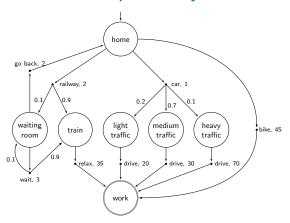

Solution 2: traveling without taking too many risks

Most bosses will not be happy if we are late too often...

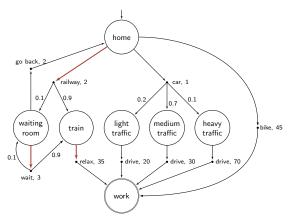

what if we are risk-averse and want to avoid that?

Solution 2: maximize the probability to be on time

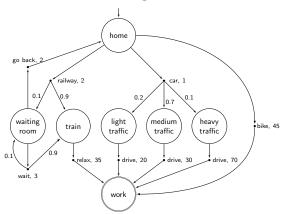

Specification: reach work within 40 minutes with 0.95 probability

Solution 2: maximize the *probability* to be on time

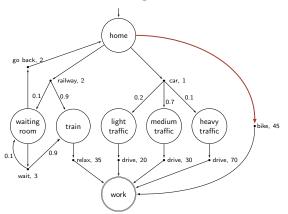

Specification: reach work within 40 minutes with 0.95 probability **Sample strategy**: take the **train** $\rightsquigarrow \mathbb{P}_D^{\sigma} \big[\mathsf{TS}^{\mathsf{work}} \leq 40 \big] = 0.99$ **Bad choices**: car (0.9) and bike (0.0)

Solution 3: strict worst-case guarantees

Specification: *guarantee* that work is reached within 60 minutes (to avoid missing an important meeting)

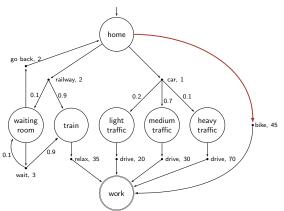

Solution 3: strict worst-case guarantees

Specification: *guarantee* that work is reached within 60 minutes (to avoid missing an important meeting)

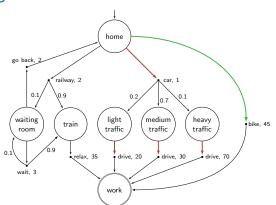

Sample strategy: bike \sim worst-case reaching time = 45 minutes. Bad choices: train ($wc = \infty$) and car (wc = 71)

Solution 3: strict worst-case guarantees

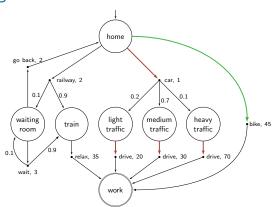

Worst-case analysis \sim two-player game against an antagonistic adversary (bad guy)

Solution 4: minimize the *expected* time under strict worst-case guarantees

- Expected time: car $\sim \mathbb{E} = 33$ but wc = 71 > 60
- Worst-case: bike $\rightsquigarrow wc = 45 < 60$ but $\mathbb{E} = 45 >>> 33$

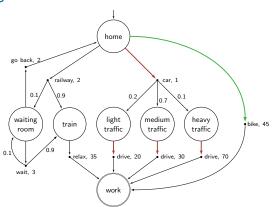

Solution 4: minimize the *expected* time under strict worst-case guarantees

In practice, we want both! Can we do better?

▶ Beyond worst-case synthesis [BFRR14b, BFRR14a]: minimize the expected time under the worst-case constraint.

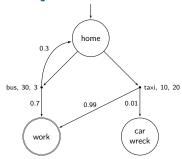

Solution 4: minimize the *expected* time under strict worst-case guarantees

Sample strategy: try train up to 3 delays then switch to bike.

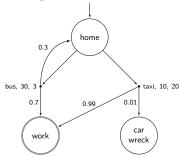

- \rightarrow wc = 58 < 60 and $\mathbb{E} \approx 37.34 << 45$
- → Strategies need memory → more complex!

Solution 5: multiple objectives ⇒ trade-offs

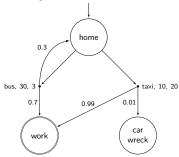

Two-dimensional weights on actions: time and cost.

Often necessary to consider trade-offs: e.g., between the probability to reach work in due time and the risks of an expensive journey.

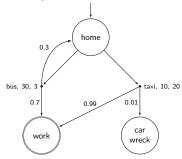

Solution 2 (probability) can only ensure a single constraint.

- C1: 80% of runs reach work in at most 40 minutes.
 - ightharpoonup Taxi ightharpoonup ≤ 10 minutes with probability 0.99 > 0.8.

Solution 2 (probability) can only ensure a single constraint.

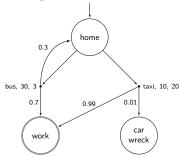

- C1: 80% of runs reach work in at most 40 minutes.
 - ightharpoonup Taxi ightharpoonup ≤ 10 minutes with probability 0.99 > 0.8.
- **C2**: 50% of them cost at most 10\$ to reach work.
 - \triangleright Bus \rightarrow > 70% of the runs reach work for 3\$.

Solution 2 (probability) can only ensure a single constraint.

- C1: 80% of runs reach work in at most 40 minutes.
 - \triangleright Taxi \rightarrow ≤ 10 minutes with probability 0.99 > 0.8.
- C2: 50% of them cost at most 10\$ to reach work.
 - \triangleright Bus $\rightsquigarrow \ge 70\%$ of the runs reach work for 3\$.

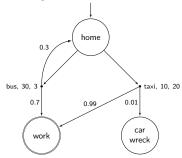

Taxi $\not\models$ C2, bus $\not\models$ C1. What if we want C1 \land C2?

- C1: 80% of runs reach work in at most 40 minutes.
- **C2**: 50% of them cost at most 10\$ to reach work.

Study of multi-constraint percentile queries [RRS15a].

- Sample strategy: bus once, then taxi. Requires memory.
- Another strategy: bus with probability 3/5, taxi with probability 2/5. Requires *randomness*.

- C1: 80% of runs reach work in at most 40 minutes.
- C2: 50% of them cost at most 10\$ to reach work.

Study of multi-constraint percentile queries [RRS15a].

In general, both memory and randomness are required.

≠ previous problems ~ more complex!

Conclusion (1/3)

This talk was about **shortest path objectives**, but there are many more! Some examples based on energy applications.

- Energy: operate with a (bounded) fuel tank and never run out of fuel [BFL⁺08].
- ▶ Mean-payoff: average cost/reward (or energy consumption) per action in the long run [EM79].
- ▶ Average-energy: energy objective + optimize the long-run average amount of fuel in the tank [BMR+15].

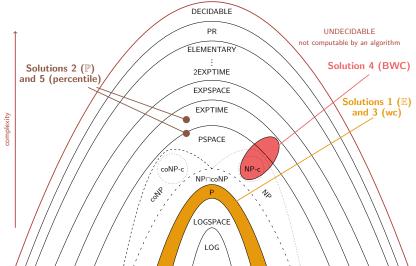

Conclusion (2/3)

Our research aims at:

- defining meaningful strategy concepts,
- providing algorithms and tools to compute those strategies,
- classifying the *complexity* of the different problems from a theoretical standpoint.
 - → Is it mathematically possible to obtain efficient algorithms?

Conclusion (3/3)

Algorithmic complexity: hierarchy of problems (for shortest path)

Thank you! Any question?
